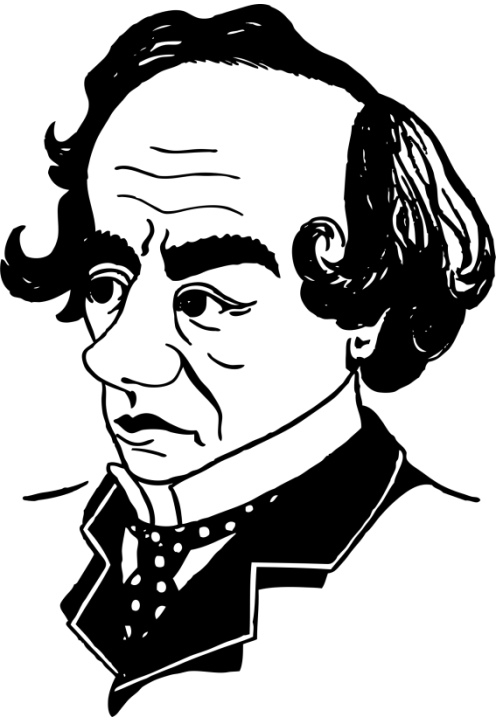
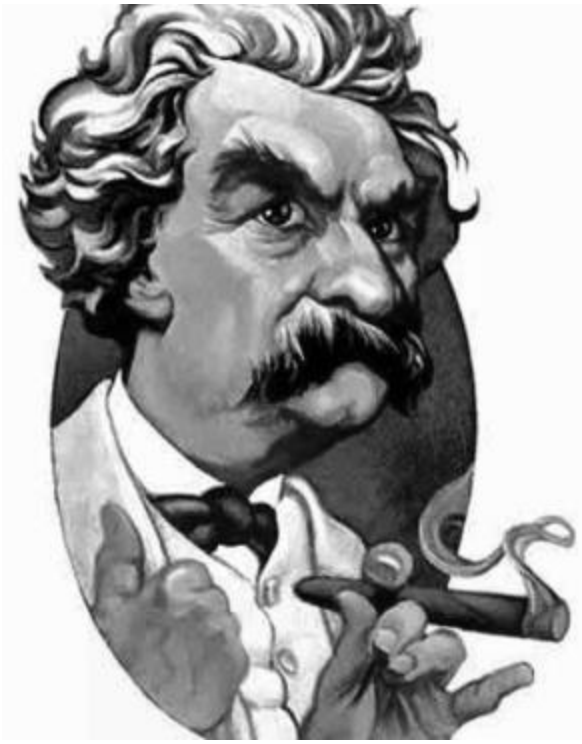
Statistical Faux Pas

Statistical Faux Pas

- **There are three kinds of lies: lies, damned lies, and statistics. (Attributed by Mark Twain to B. Disraeli)**



Benjamin Disraeli



Mark Twain

Facts *vs.* Hypotheses

Facts before Hypotheses!

"It is a capital mistake to theorize before one has data. Insensibly one begins to twist facts to suit theories, instead of theories to suit facts."

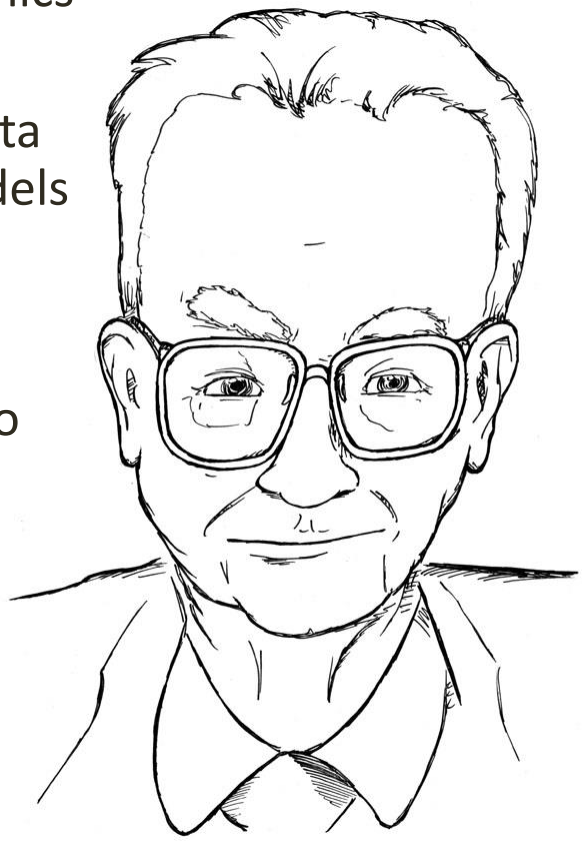
Sir Arthur Conan Doyle as the character of Sherlock Holmes

Facts *vs.* Hypotheses

Facts before Hypotheses!

- "If you torture the data long enough, it will confess," Ronald Coase, Nobel Prize in Economics

- Scientists are not interested in the data for data sake. Scientists want to use data to build models that help us understand nature. Good hypotheses are hard to come by and in my experience, some scientists have twisted interpretations of their experimental results to support their pet hypotheses.



Facts *vs.* Hypotheses

Facts before Hypotheses!

In a nursing school we found that if the student's race was "Missing" then the students were more likely to dropout.

At first, we thought that this missing race information indicated that their was an ethnicity that pre-disposed these students to drop out.

But, we could not find any ethnicity that had a significantly higher retention or dropout rate.

In fact, further investigation revealed that the proportion of ethnicities was the same for the overall student population and those students whose race was categorized as "Missing".

Later, we determined that most of the students who filled out the forms themselves did not enter information on their ethnicity. In these cases, the student's race was "Missing". All students who were personally assisted by a (diligent) registrar entered a value for race. Further analysis indicated that personal assistance by a registrar, regardless of race, correlated with high retention rate.

We should have collected more facts before we created our hypotheses

Facts *vs.* Hypotheses

- One might conclude: Facts before Hypotheses!

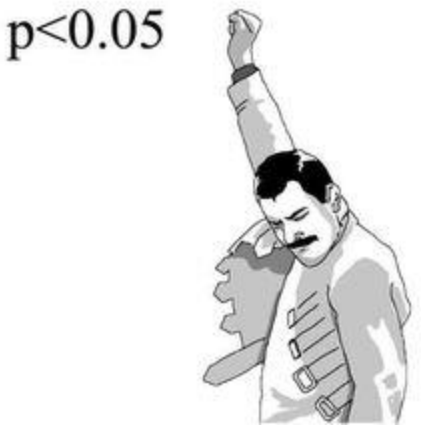
- On the other hand, there are arguments for Hypotheses before Facts:
  - We need hypotheses to guide research. Without a hypothesis we wouldn't know what to data to collect.
  - Hypotheses before Facts prevents cherry picking or shot-gunning of hypotheses until a hypothesis fits.

- Could we use Facts before Hypotheses and then use the p-value to determine if a hypothesis is good?

Misuse of p-Value

Hypotheses before Facts!

- How is p-value misused?
  - Shot gunning or cherry picking hypotheses
  - Misunderstanding the nature of a p-value.



Misuse of p-Value

Hypotheses before Facts!

- How is p-value misused?
  - Do Jelly Beans Cause Acne with $p < 0.05$? http://xkcd.com/882/
  - The null hypothesis states that the observed variations do not follow the hypothesis. As you investigate more and more hypotheses, there is an increasing chance that you will find a null hypothesis that has a low p-value.
  - Commonly we use a p-value of < 0.05. That means that there is "only" a 5% chance that the null hypothesis is true.
  - If the observed p-value < 0.05, then we might mistakenly assume that there is a 95% chance that the hypothesis accounts for the observations.
  - How many hypotheses (n) should we test if we want a more than even (50%) chance to find 1 or more p-values (p) at less than 5% from random data?
    - $0.5 < 1 - (1 - p)^n$; for p = 0.05 we find: n ≥ 14

Misuse of p-Value

Hypotheses before Facts!

How is p-value misused?

Misuse of p-values and experimental design

- After a large, epidemiological study failed to support a hypothesis, the researchers wanted to justify their grant. They looked for any pattern in their data. They transformed their data in as many ways as they could to find a pattern.
- When they found a pattern they retrospectively formulated a hypothesis and then they determined if that hypothesis had a p-value < 0.05, as is common in such studies. A p-value < 0.05 means that there is only a 5% probability that the null hypothesis accounts for the patterns.
- The researchers announced many (50) hypotheses that were "verified" by this method. Soon colleagues educated them: Constructing a post-facto hypothesis, is similar to re-using training data as testing data.
- Then the researchers randomly partitioned their data into a pattern search dataset and a pattern corroboration dataset. Although, they corroborated 1 of the patterns, this search was still statistically insignificant because we expect that about 5% of the null hypotheses have a p-value < 0.05 .

Misuse of p-Value

Hypotheses before Facts!

- How do you get a "p < 0.05"? Answer: Ask lots of questions.
- Stanly Young
- http://www.dcscience.net/Young-Karr-2011.pdf

Misuse of p-Value

Clarify p-Value!

- How can we fix the problem?
- Statisticians need to explain the p-value to us.

- The following slides are adapted from a paper by Christie Ashwanden :

Statisticians Found One Thing They Can Agree On: It's Time To Stop Misusing p-values

http://fivethirtyeight.com/features/statisticians-found-one-thing-they-can-agree-on-its-time-to-stop-misusing-p-values/

Misuse of p-Value

Clarify p-Value!

- How can we fix the problem?
- Statisticians need to explain the p-value to us.

Definition by Statisticians to layman:
Informally, a p-value is the probability under a specified statistical model that a statistical summary of the data (for example, the sample mean difference between two compared groups) would be equal to or more extreme than its observed value.

Misuse of p-Value

Clarify p-Value!

- How can we fix the problem?
- Statisticians need to explain the p-value to us.

"That definition is about as clear as mud"

Definition by Statisticians to layman:
Informally, a p-value is the probability under a specified statistical model that a statistical summary of the data (for example, the sample mean difference between two compared groups) would be equal to or more extreme than its observed value.

"... even scientists can't easily explain p-values"

Misuse of p-Value

Clarify p-Value!

Observational Studies

Problems with Observational Studies

- If we have a problem with collecting facts before developing a hypothesis and we have a problem with developing a hypothesis before collecting facts, then we may want to observe and draw conclusions from observational studies.
- In Search of Excellence (1982) one of the most popular business books of all time. Studied 44 successful "excellent" companies.
- 5 years later 65% of the companies did worse than the S&P 500 Index
- The case study method makes for a good story, but it's not good science. The problems are typically small sample sizes and , numerous biases like survivorship and extreme cases.

Observational Studies

Problems with Observational Studies

- "Any claim coming from an observational study is most likely to be wrong" (Stanley Young)
- Young and Karr looked at 52 similar published epidemiological findings that were followed by a clinical trial testing the result.
- NONE of the 52 claims replicated in the clinical trials! (5 were significant in the opposite direction.)

Observational Studies

Problems with Observational Studies

- Wrong results from an observational study could be
  - Innocent
  - Not so innocent – sort through the data to find evidence to prove your case and ignore all the other signals
- How to determine if it's a real insight?
  - Test it – conduct a valid experiment to see if the presumed cause and effect relationship holds (e.g. clinical trial, design of experiments)
  - Get additional, independent data sets and see if the relationship is still present
  - Caution: Most analyses only validate the presence of a relationship. Most analyses do not even show that a cause and effect relationship exist. And, even if a cause and effect relationship exists, we might not know which is cause and which is effect.
  - Never allow the same data to suggest a relationship AND validate it.

Descriptive Measures

Beware of Descriptive Measures

- We need to understand our data better before we make conclusions.
- We can use descriptive measures to help us understand our data

Descriptive Measures

Beware of Descriptive Measures

We have 6 measures of a dataset.

Property	Value
mean(y)	9
var(x)	11
mean(y)	7.50
var(y)	4.125
corrcoef(x,y)	0.816
LinearRegression	y = 3 + 0.5x

What does the dataset look like?
Do the data have outliers?
Do the data form a linear relationship?
Can we extrapolate from this relationship?

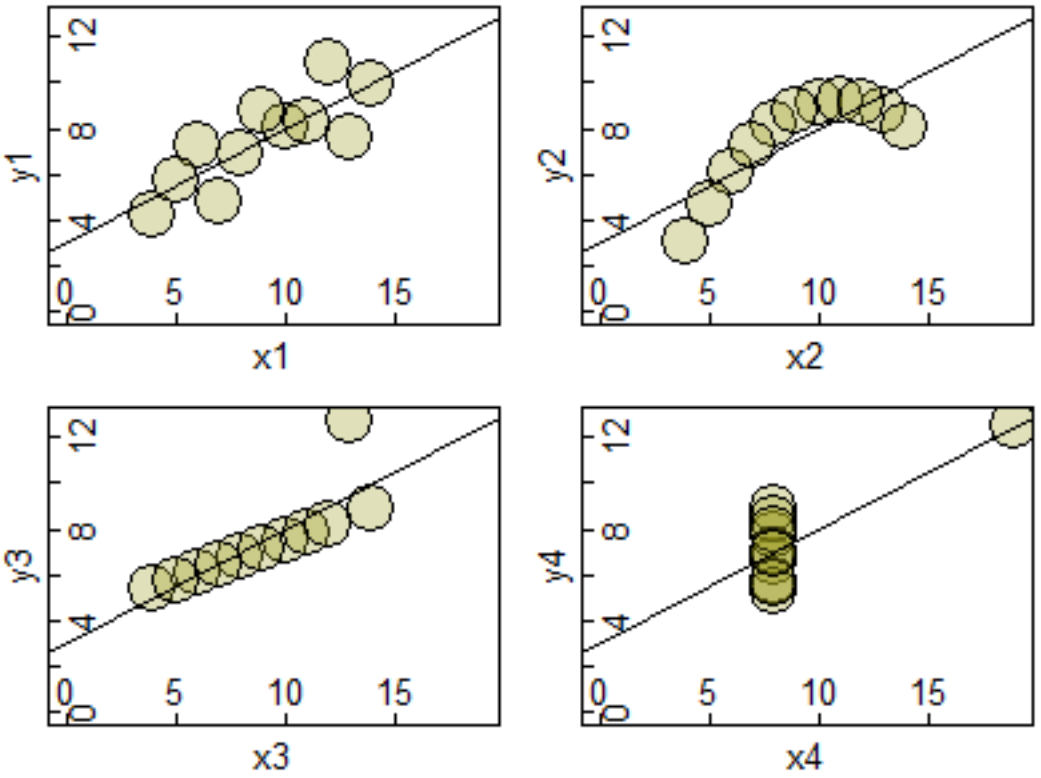
Descriptive Measures

Beware of Descriptive Measures

We have 6 measures of a dataset.

Property	Value
mean(y)	9
var(x)	11
mean(y)	7.50
var(y)	4.125
corrcoef(x,y)	0.816
LinearRegression	y = 3 + 0.5x

What does the dataset look like?
Do the data have outliers?
Do the data form a linear relationship?
Can we extrapolate from this relationship?



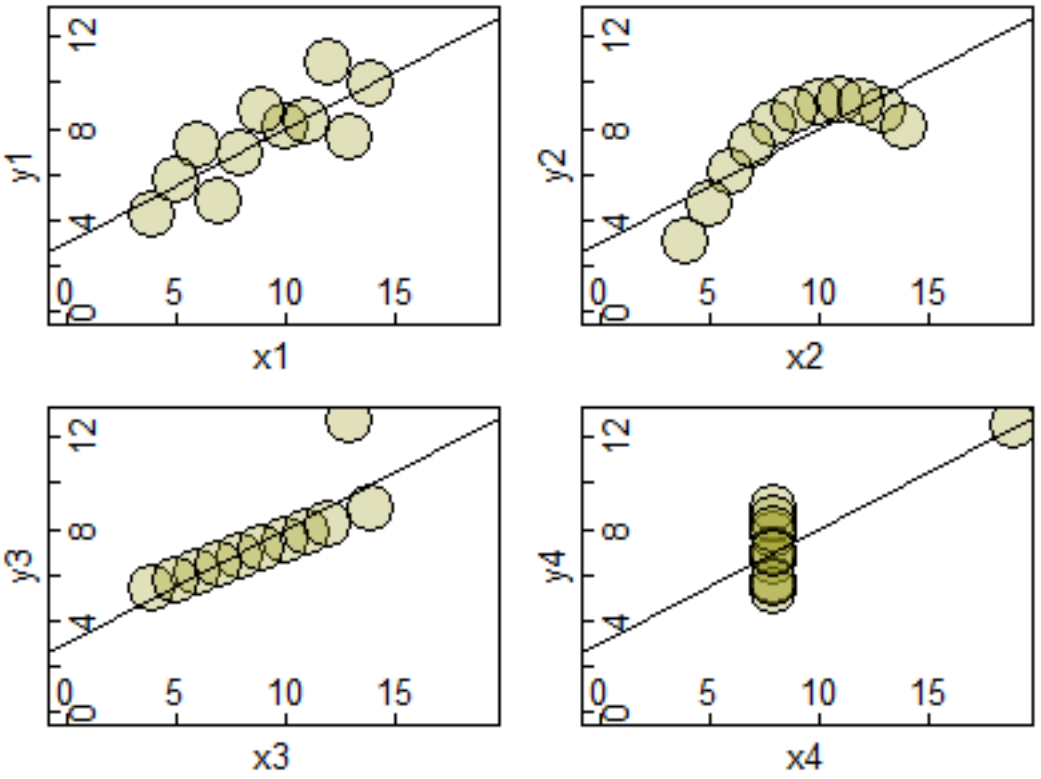
Descriptive Measures

Beware of Descriptive Measures

We have 6 measures of a dataset.

Property	Value
mean(y)	9
var(x)	11
mean(y)	7.50
var(y)	4.125
corrcoef(x,y)	0.816
LinearRegression	y = 3 + 0.5x

What does the dataset look like?
Do the data have outliers?
Do the data form a linear relationship?
Can we extrapolate from this relationship?



Which of these 4 data sets belongs to these measurements?

Descriptive Measures

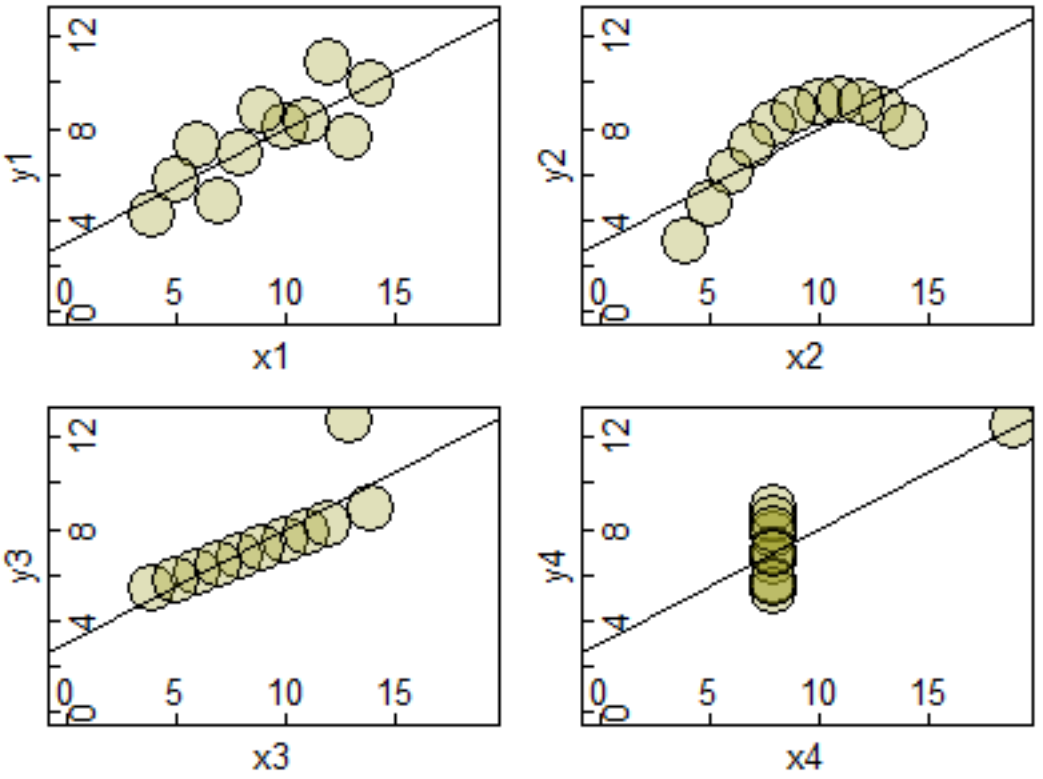
Reliance on Descriptive Measures

We have 6 measures of a dataset.

Property	Value
mean(y)	9
var(x)	11
mean(y)	7.50
var(y)	4.125
corrcoef(x,y)	0.816
LinearRegression	y = 3 + 0.5x

All these data sets have these measurements!

Anscombe's Quartet
See: AnscombeQuartet.R
https://en.wikipedia.org/wiki/Anscombe%27s_quartet



Performance Expectations

Is the past representative of the future?

- Other problems may arise due to expectations of future performance.

Performance Expectations

Is the past representative of the future?

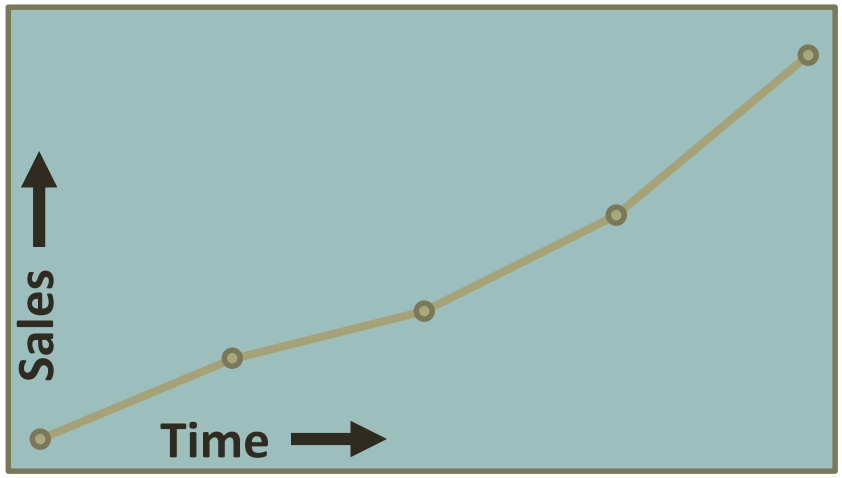
- Management complains: "Our top 1000 customers in 2014 bought 20% less in 2015"
- Management assumes that these customers were disappointed. But, a reduction is expected. The phenomenon is known as "regression to the mean"
- If a measurement of a variable is observed to be extreme, and there is no trend, it will tend to be closer to the average on the next measurement
- Examples:
  - Performance Reviews
  - Sales by Account Managers
  - Sports Illustrated Jinx

- ("Regression to the mean" is the origin of the word regression as in linear regression.)

Performance Expectations

Interpreting Recent Trends

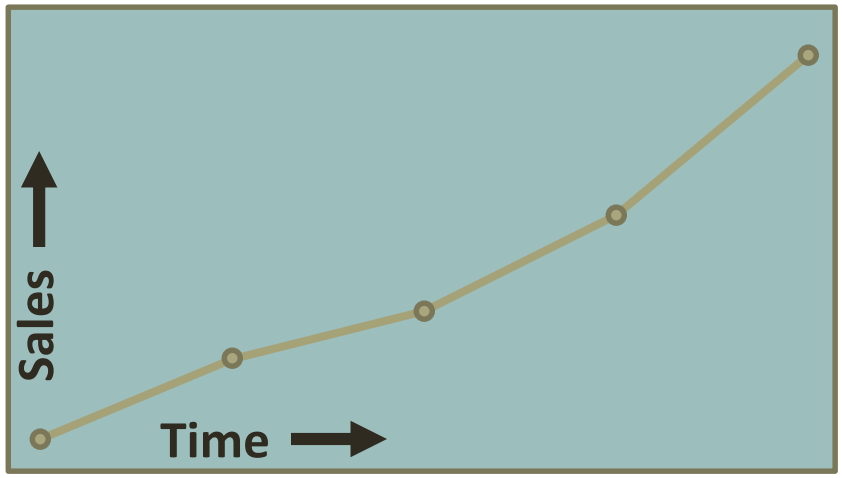
- Sales have increased for the past four months in a row. Are we on a meaningful trend? What are the chances?



Performance Expectations

Interpreting Recent Trends

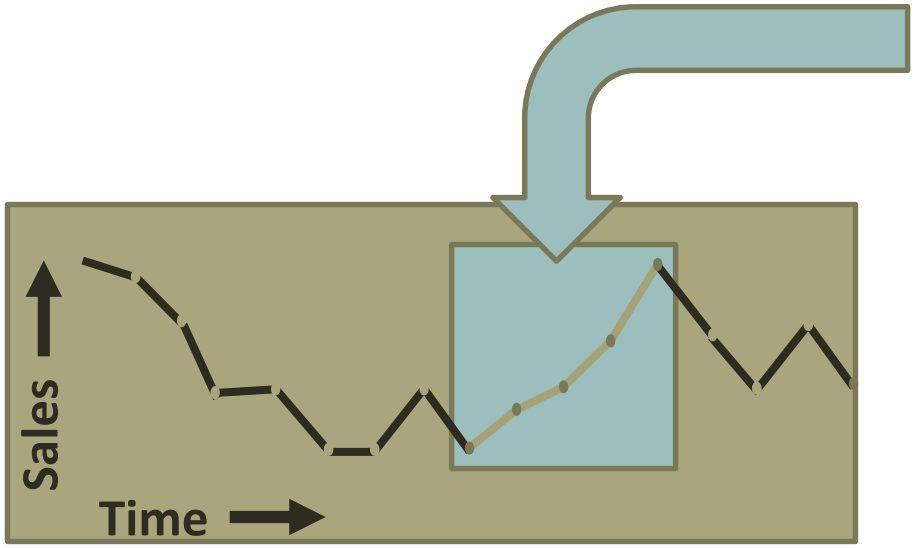
- Sales have increased for the past four months in a row. Are we on a meaningful trend? What are the chances?
- 5 monthly measurements where each successive measurement increased:
- Probability of a random occurrence if increase and decrease are equally likely: ½ * ½ * ½ * ½ = 6%

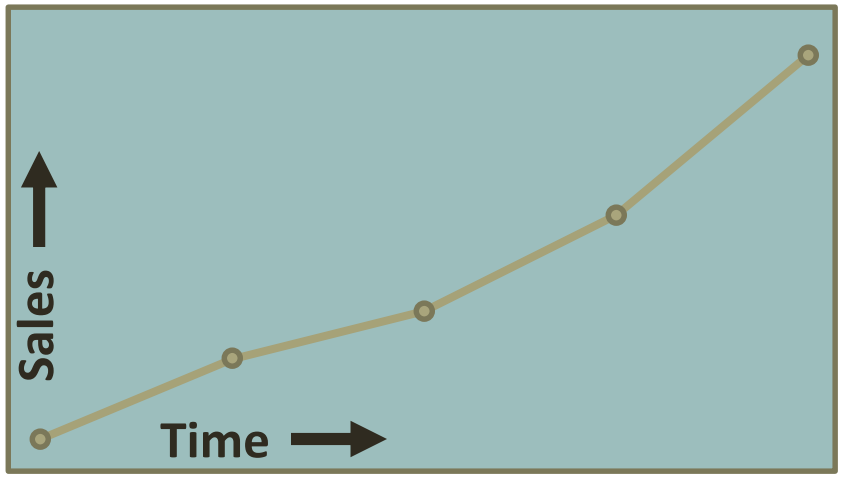


Performance Expectations

Interpreting Recent Trends

- Sales have increased for the past four months in a row. Are we on a meaningful trend? What are the chances in a year?

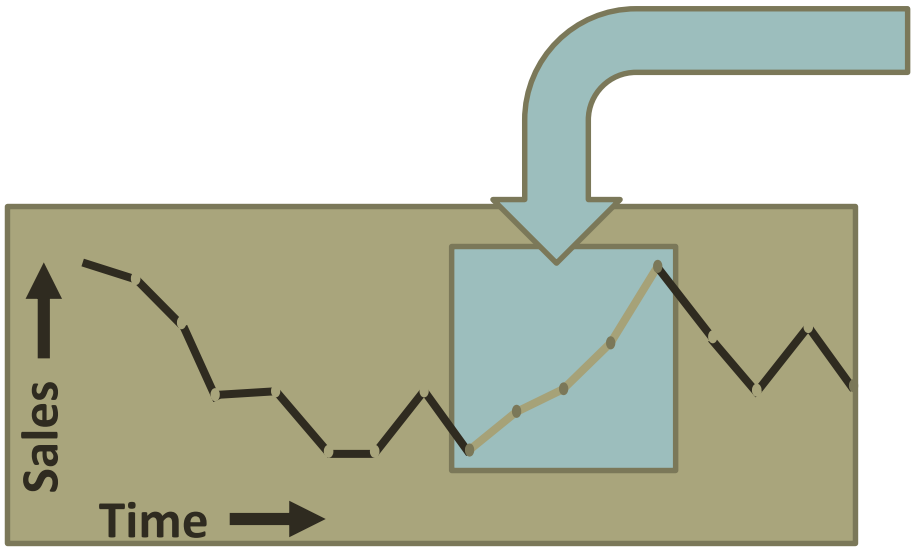


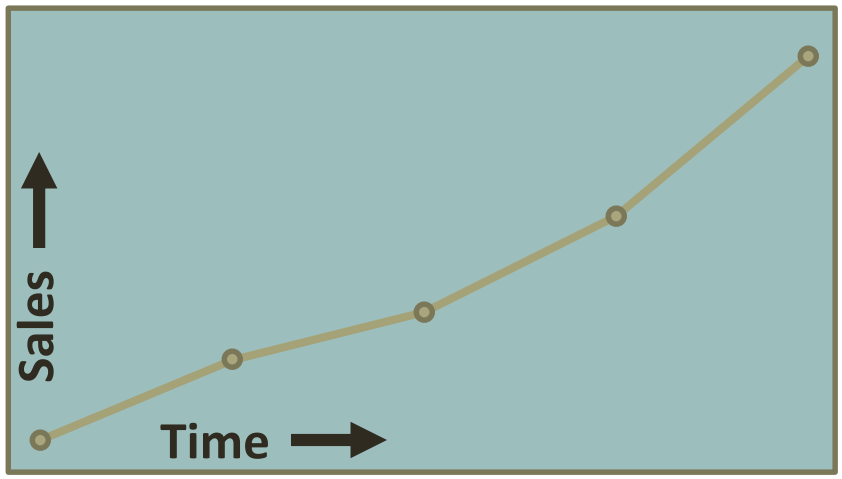


Performance Expectations

Interpreting Recent Trends

- Sales have increased for the past four months in a row. Are we on a meaningful trend? What are the chances in a year?
  - 9 sequences of 4 changes: 0-4, 1-5, …, 8-12
  - 4 sequential increases
  - $1 - (1 - 2^{-4})^{9} = 0.44$
- In a year there is a 44% chance of 4 sequential increases.





Correlation *vs.* Causation

Most Statistics analyzes correlation not causation!

- A common human trait is to observe two things occurring together and assume one is causing the other
- Examples:
  - Leading Economic Indicators
  - Bad Breath and Heart Disease

- An observed (statistically significant) relationship may be due to
  - Happenstance (i.e. chance or co-incidence)
  - Statistical significance helps, but among 100 relationships with p=0.05, odds are that about 5 will be by chance.
  - Common hidden factor
  - True cause-effect relationship but which direction?

Spurious Relationship

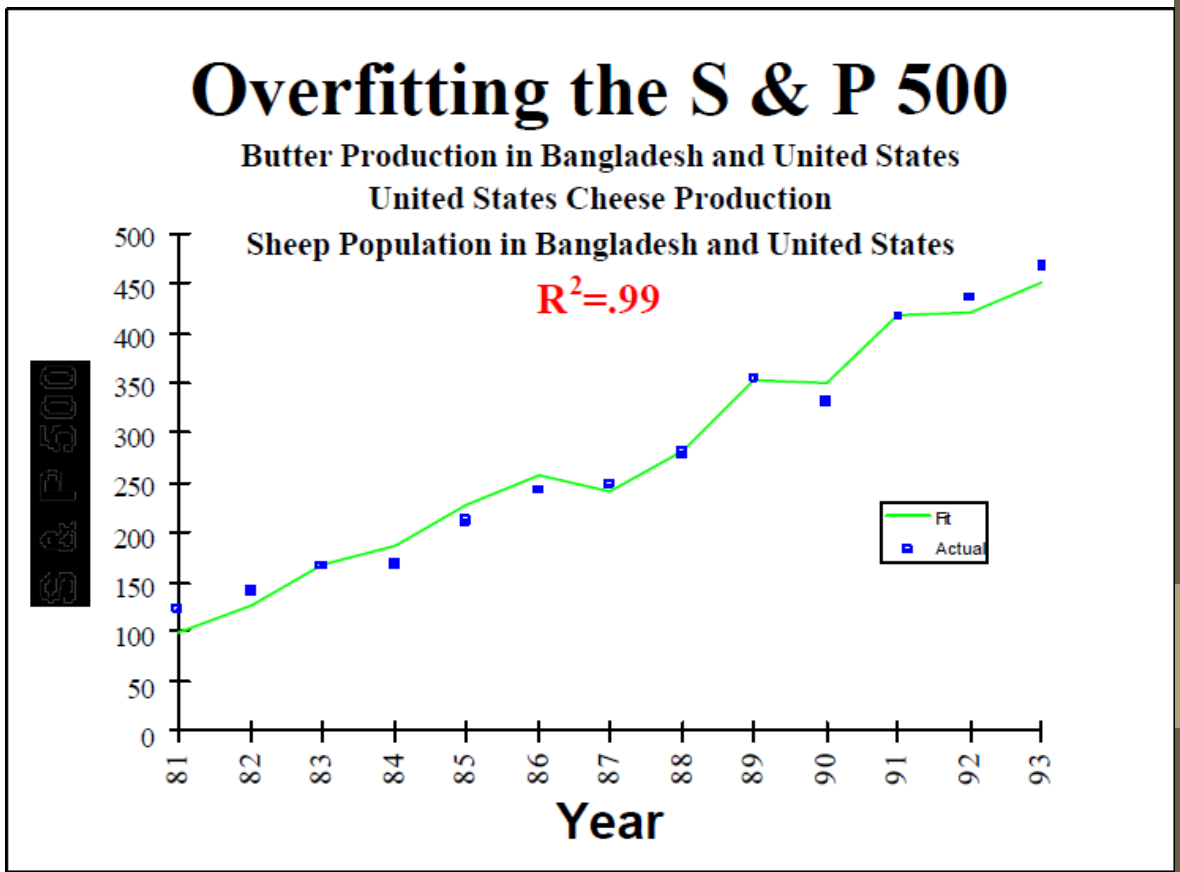
Relationships may be happenstance

https://en.wikipedia.org/wiki/Spurious_relationship

Spurious Relationship

Relationships may be happenstance

Exact prediction of S&P 500 returns by Ivan O. Kitov, Oleg I. Kitov (See: SSRN-id1045281.pdf)



Spurious Relationship

Relationships may be happenstance

- Redskins Rule (http://en.wikipedia.org/wiki/Redskins_Rule)
  - http://abbottanalytics.blogspot.com/2012/11/why-predictive-modelers-should-be.html

"Our algorithms have linked funny cat videos, UFO reports and searches for tofu pizza. We're now on alert about a suspicious group of cat aliens who infiltrated our pizza industry."

Hidden Proxies

Beware of target leakage

- We were using predictive analytics to look for causes of dropouts in a nursing school.
- At one point we looked for professors who were associated with high dropouts or high retention.
- We found one professor whose students had a 100% retention rate. We thought that this result was significant.
- It turned out that this professor had the final class in this two-year program. In other words, drop-outs occurred prior to this professor's class. In fact her class was a pro-seminar and all the students for this class had essentially already graduated.

Hidden Proxies

Beware of target leakage

- Proxies and Audience Gullibility:
- Scam artists use proxy attributes in their “predictions”
- A true story from about 20 years ago:
  - A fortune teller went on a radio talk show on KGO in the Bay Area.
  - He demonstrated how he could mimic psychic abilities by getting people to divulge information without their knowledge.
  - After the show, this confessed scam artist was flooded with requests for psychic readings.
  - The audience preferred to believe in his psychic powers and not his confessions.

Selective Presentation

Selective Presentation of Outcomes

- In the 1950's, a convict in Italy, wrote to 80 stockbrokers from prison. He claimed to have insider information from a fellow convict who had been an executive at a local company.
- To 40 stockbrokers he wrote that the stock price would rise in the next two days. To the other 40 stockbrokers he wrote that the stock price would fall.
- After two days he followed up letters to the 40 stockbrokers who received the correct prediction. To half of those he wrote that the stock price would rise and to the other half he wrote that the stock price would fall.
- The prisoner repeated this pattern three more times and then requested a fee from the stockbrokers for additional predictions.

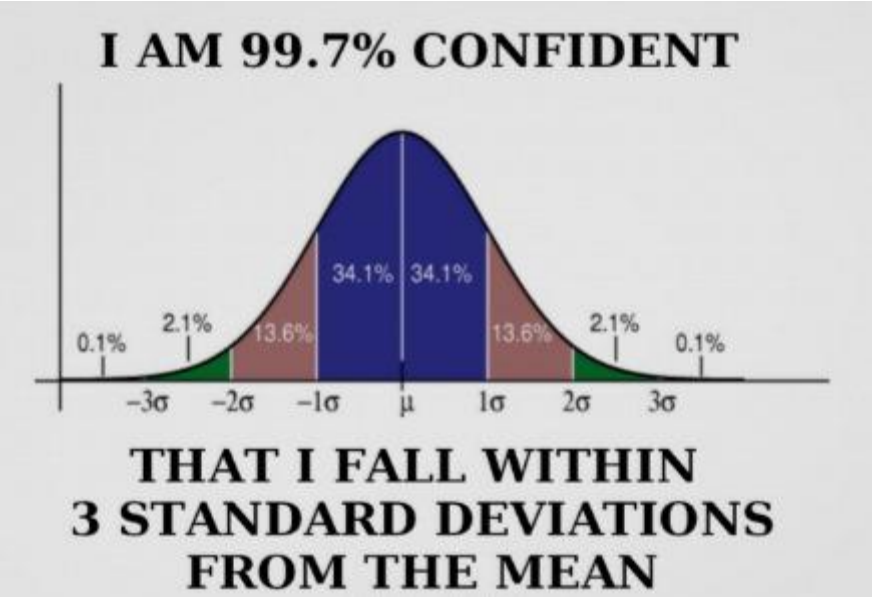
Superstition

Superstition

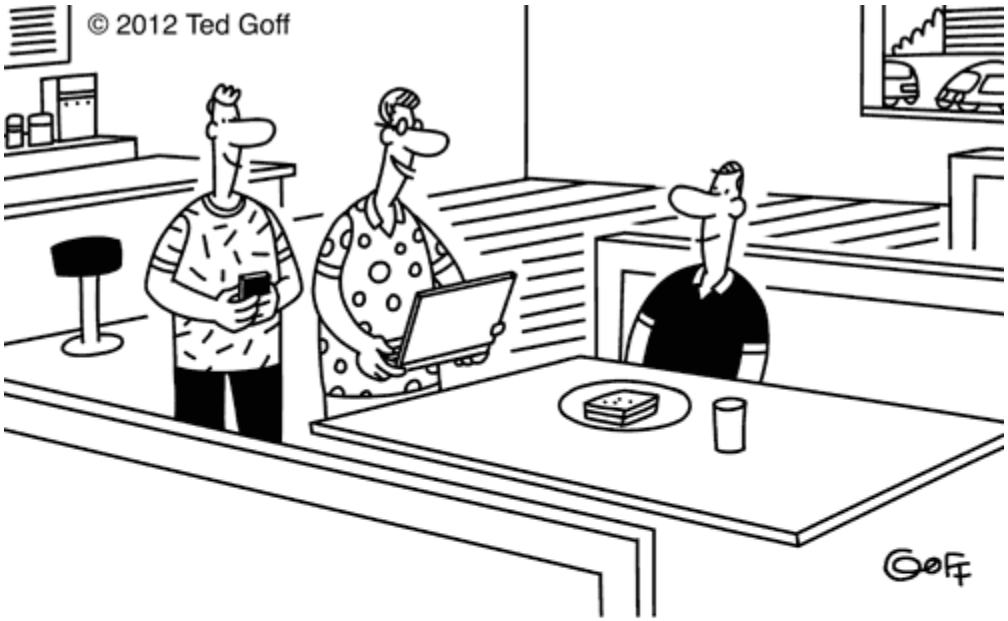
- HBR Superstitious Learning
- "Superstitious learning takes place when the connection between the cause of an action and the outcomes experienced aren't clear, or are misattributed."
- Some Causes:
  - Expecting high/low performance to remain at that level
  - Interpreting trends that could be due to randomness
  - One-off occurrences
  - Causation inferred from correlation

Tautology

Tautology



Statistical Faux Pas



"Twitter and Facebook can't predict the election, but they did predict what you're going to have for lunch: a tuna salad sandwich. You're having the wrong sandwich."

Simpson's Paradox

Simpson's Paradox

- A trend appears in different groups of data but disappears or reverses when these groups are combined.
- Simpson, E.H. (1951) The interpretation of interaction in contingency tables. Journal of the Royal Statistical Society, Ser B, 13, 238-241
